

Assignment Title:

Coursework 2

Coursework Type:

Individual

Module Name:

STW220CT: Data and Information Retrieval

Intake:

MARCH 2020

Submitted By

CU ID: 10272453

College ID: 180072

Name: Sayyed Abrar Akhtar

Table of Contents

Task 1: MongoDB	5
1. Create a database named <<YourName_Games>> and a collection named <<YourName_CoventryID_Games>> and insert the above data.....	5
2. What is Map-Reduce? Explain the working of map-reduce with an example.....	13
3. Write a reduce function that calculates the total score for each team with the publisher name and count the number of players in each team.....	15
4. Count the number of players in Hays Wise.	17
5. Remove the player "Alpha" from Ape Escape.	18
6. Update the player name "Jordan" to "Michael" and score to 300.....	19
7. Show all the number of players with their publisher name.	20
8. Show total goals scored by each country name.	21
Task 2: Development of a graph database for a given dataset.	22
1. Create a Data Model diagram for "Task_2_PremierLeague_2019.csv" dataset.	22
2. Create nodes and relationship according to the Data Model which you have created in question no. 1.	23
3. Show all the EPL team involved in the season.....	25
4. Count all the matches refereed by each referee.	26
5. Who refereed the most matches?	28
6. How many matches "Arsenal" won as the away team?	28
7. Display all the matches that "Man United" lost.	29
8. Display all the matches that "Liverpool" won but were down in the first half.	29
Task 3:	30
"Column-oriented storage in a database system are more suitable for analytical reporting than the row-oriented database." Justify this statement with suitable example.....	30

Figure 4: Collection created

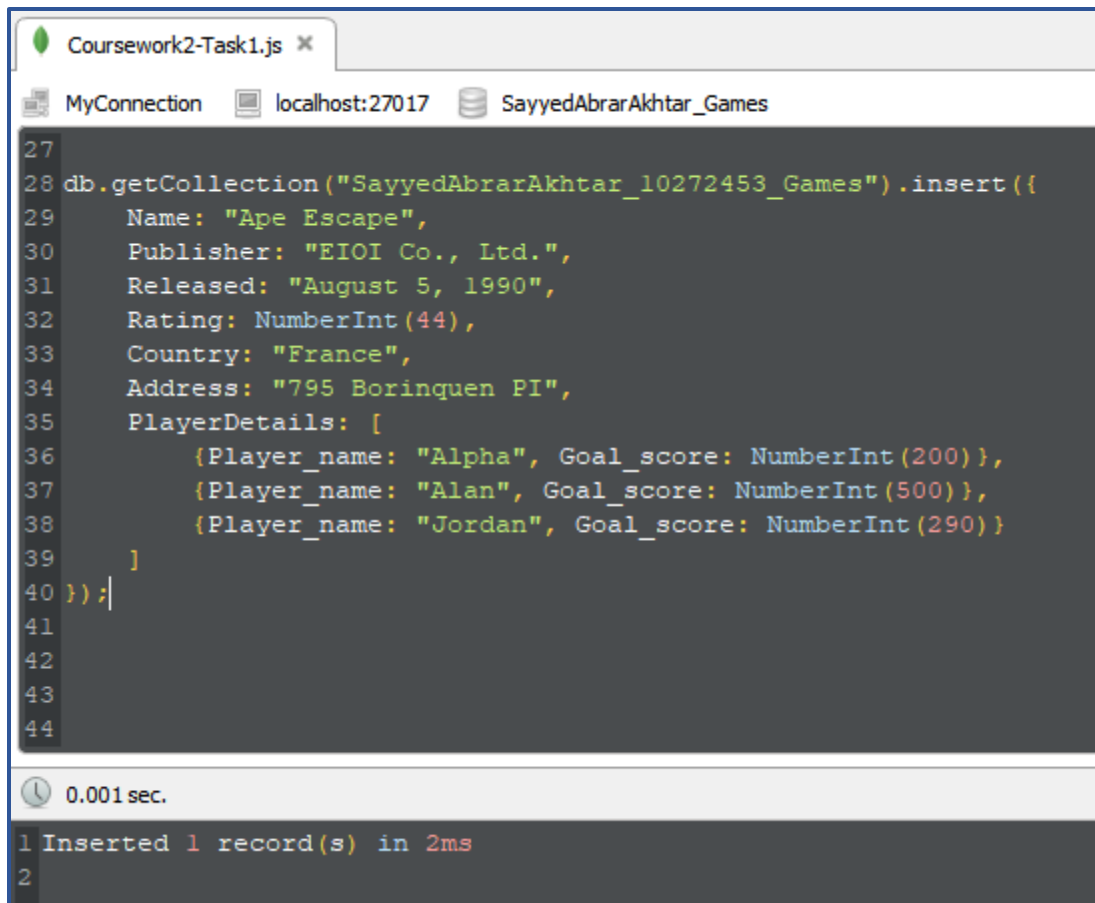

The screenshot shows a web browser window with the title "Coursework2-Task1.js". The address bar displays "localhost:27017" and the database name "SayyedAbrarAkhtar_Games". The console shows a JavaScript query to insert a record into a MongoDB collection. The query is as follows:

```
13 // Insert data
14 db.getCollection("SayyedAbrarAkhtar_10272453_Games").insert({
15     Name: "Hays Wise",
16     Publisher: "KOEI Co., Ltd.",
17     Released: "April 5, 1990",
18     Rating: NumberInt(99),
19     Country: "USA",
20     Address: "694 Hewes Street",
21     PlayerDetails: [
22         {Player_name: "Derrick", Goal_score: NumberInt(705)},
23         {Player_name: "Tim", Goal_score: NumberInt(379)},
24         {Player_name: "Bryan", Goal_score: NumberInt(810)}
25     ]
26 });
27
28
29
30
```

The execution time is shown as "0.001 sec.". The result of the query is "1 Inserted 1 record(s) in 1ms".

Figure 5: Query to insert first record

The screenshot shows a MongoDB console window with the following elements:

- Tab:** Coursework2-Task1.js
- Connections:** MyConnection, localhost:27017, SayyedAbrarAkhtar_Games
- Code Editor:** Contains a JavaScript query to insert a document into the 'SayyedAbrarAkhtar_10272453_Games' collection. The document includes fields for Name, Publisher, Released, Rating, Country, Address, and an array of PlayerDetails.
- Execution Bar:** Shows a clock icon and the execution time '0.001 sec.'.
- Output:** A message indicating '1 Inserted 1 record(s) in 2ms'.

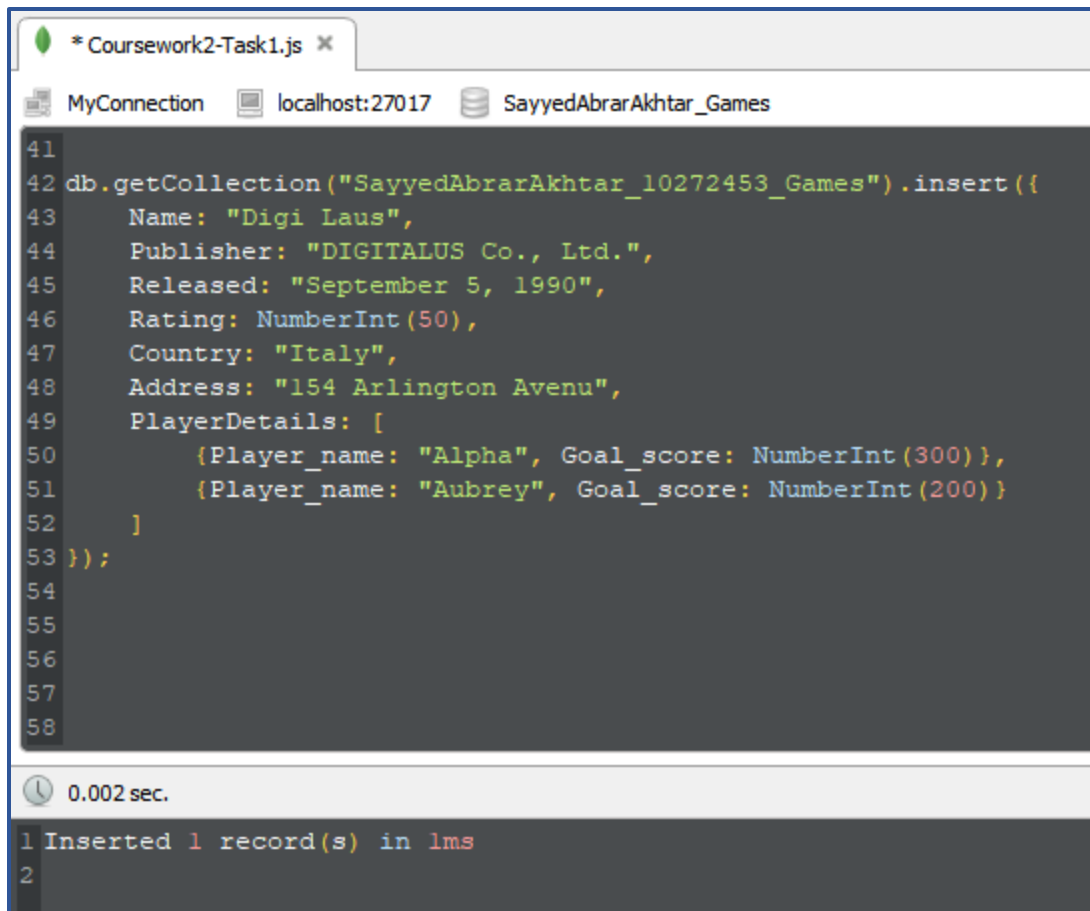

```
27
28 db.getCollection("SayyedAbrarAkhtar_10272453_Games").insert({
29   Name: "Ape Escape",
30   Publisher: "EIOI Co., Ltd.",
31   Released: "August 5, 1990",
32   Rating: NumberInt(44),
33   Country: "France",
34   Address: "795 Borinquen PI",
35   PlayerDetails: [
36     {Player_name: "Alpha", Goal_score: NumberInt(200)},
37     {Player_name: "Alan", Goal_score: NumberInt(500)},
38     {Player_name: "Jordan", Goal_score: NumberInt(290)}
39   ]
40 });
41

0.001 sec.

1 Inserted 1 record(s) in 2ms

2

Figure 6: Query to insert second record

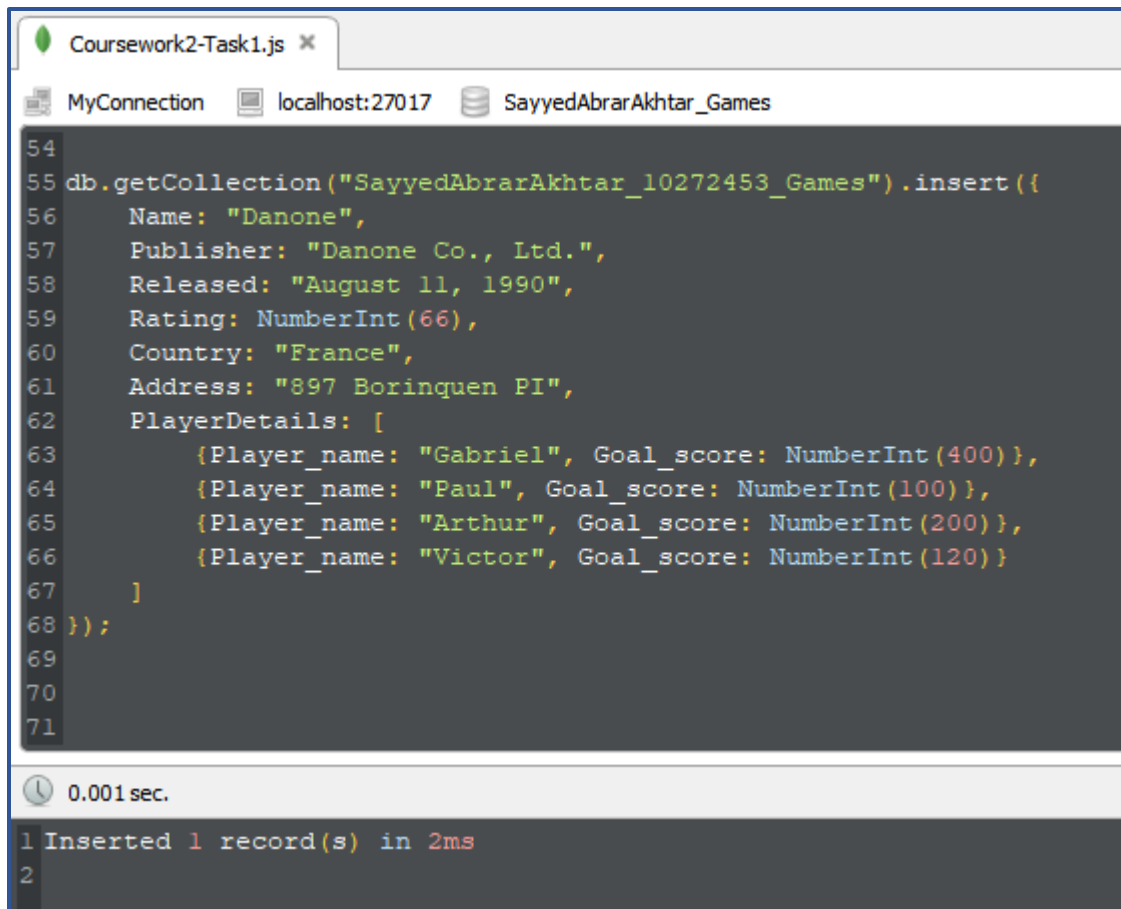

The screenshot shows a web browser window with a single tab titled '* Coursework2-Task1.js'. The address bar displays 'MyConnection', 'localhost:27017', and a database icon labeled 'SayyedAbrarAkhtar_Games'. The main content area is a dark-themed code editor showing a JavaScript query to insert a document into a MongoDB collection. The code is as follows:

```
41
42 db.getCollection("SayyedAbrarAkhtar_10272453_Games").insert({
43   Name: "Digi Laus",
44   Publisher: "DIGITALUS Co., Ltd.",
45   Released: "September 5, 1990",
46   Rating: NumberInt(50),
47   Country: "Italy",
48   Address: "154 Arlington Avenu",
49   PlayerDetails: [
50     {Player_name: "Alpha", Goal_score: NumberInt(300)},
51     {Player_name: "Aubrey", Goal_score: NumberInt(200)}
52   ]
53 });
54
55
56
57
58
```

Below the code editor, a status bar shows a clock icon and the text '0.002 sec.'. At the bottom, a console area displays the execution result:

```
1 Inserted 1 record(s) in 1ms
2
```

Figure 7: Query to insert Third record

The screenshot shows a web browser window with a single tab titled "Coursework2-Task1.js". The address bar displays "MyConnection", "localhost:27017", and a database icon labeled "SayyedAbrarAkhtar_Games". The console shows a JavaScript code snippet for inserting a document into a MongoDB collection. The code is as follows:

```
54
55 db.getCollection("SayyedAbrarAkhtar_10272453_Games").insert({
56   Name: "Danone",
57   Publisher: "Danone Co., Ltd.",
58   Released: "August 11, 1990",
59   Rating: NumberInt(66),
60   Country: "France",
61   Address: "897 Boringuen PI",
62   PlayerDetails: [
63     {Player_name: "Gabriel", Goal_score: NumberInt(400)},
64     {Player_name: "Paul", Goal_score: NumberInt(100)},
65     {Player_name: "Arthur", Goal_score: NumberInt(200)},
66     {Player_name: "Victor", Goal_score: NumberInt(120)}
67   ]
68 });
69
70
71
```

Below the code, the execution time is shown as "0.001 sec.". The output of the query is displayed in the console:

```
1 Inserted 1 record(s) in 2ms
2
```

Figure 8: Query to insert fourth record

2. What is Map-Reduce? Explain the working of map-reduce with an example.

Before the introduction of Map-Reduce, traditional approach was used for parallel and distributed processing. But traditional approach has some challenges associated with it. Some of them are:

- While processing if any function is interrupted whole process gets delayed.
- There is no management of any part of data failure.
- There was no way of dividing work into equal part to ensure machine is not overloaded.
- If working on any part of data fails whole calculation will be failed.

To overcome these challenges Map-Reduce framework is developed. It allows parallel processing solving the challenges like fault tolerance, reliability, and so on. Map-Reduce is a data processing paradigm that allows distributed and parallel processing of large datasets into useful aggregated results.

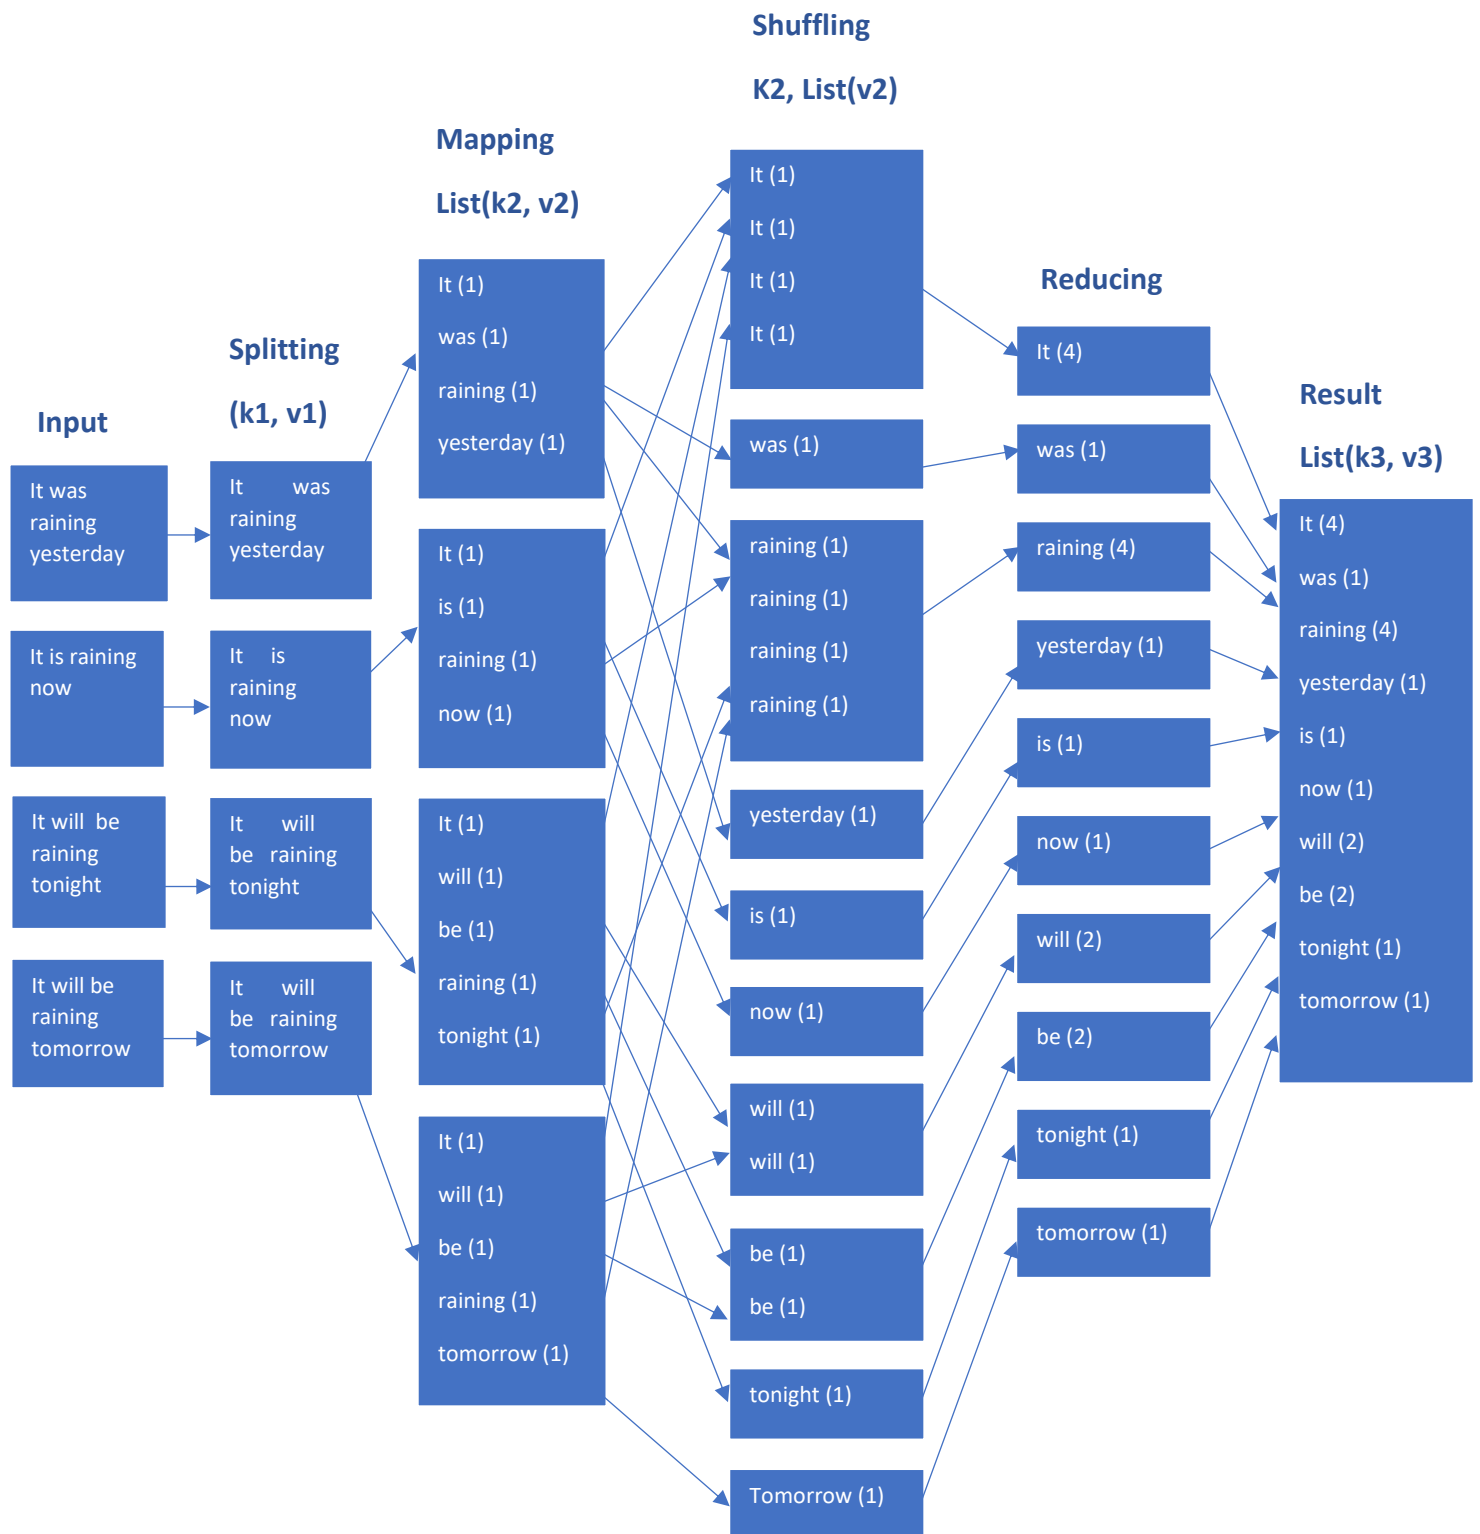

In Map-Reduce, Map is a task and Reduce is another task. Once the mapping is completed, reducing begins. In the mapping phase, block of data is read and processed to output key value pairs. The output key value pair data is served as input in the reducing phase. The reducer outputs the result aggregating those key-value pairs into key value pairs.

Example:

Map-reduce framework can be used for counting words in a paragraph or sentence. The sentences are:

- It was raining yesterday
- It is raining now
- It will be raining tonight
- It will be raining tomorrow

In order to count the words map- reduce framework input the above sentences, passes through splitting, mapping, shuffling, reducing and finally output.

The above diagram shows the map-reduce process for counting words in sentences.

Input: Sentences are provided as input.

Splitting: The input is divided into chunks as shown in the diagram above. It distributes the work among all the nodes.

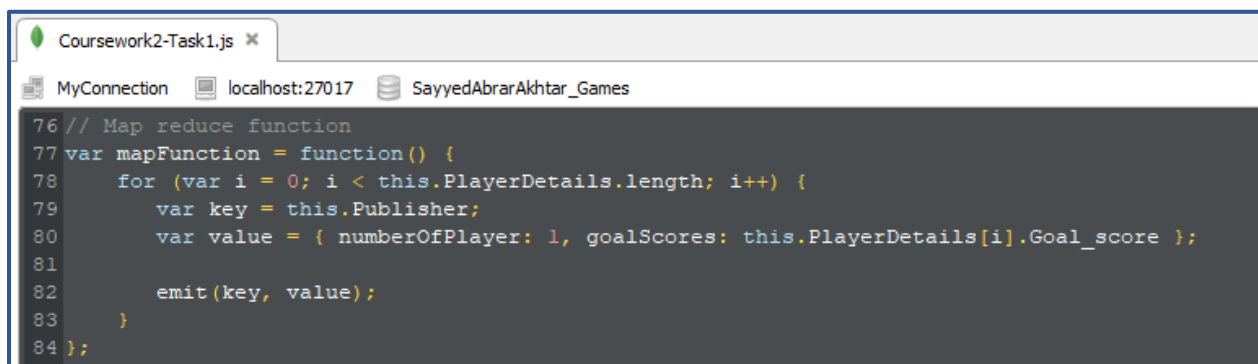

Mapping: Each word is tokenized and because they occur once in itself each token is hardcoded by value one. Thus, this makes a key value pair where key is the word itself and value (1).

Shuffling: In this stage partition process begins as well as sorting and shuffling starts to send all the list with same key to the matching reducer. It has a key and list of value matching to the key.

Reducing: In this stage reducer count the number of ones in the list as value and provides the final output where key remains the same.

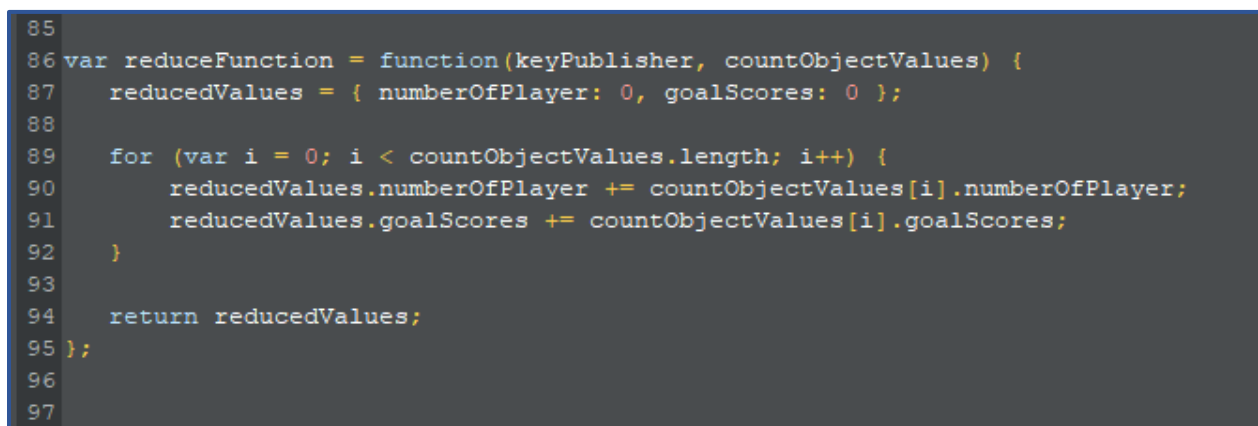

Final result: Thus, the output key value pair is returned by the reducer.

3. Write a reduce function that calculates the total score for each team with the publisher name and count the number of players in each team.

A screenshot of a code editor window titled 'Coursework2-Task1.js'. The editor shows a JavaScript function named 'mapFunction' starting at line 76. The function iterates over 'this.PlayerDetails' and emits a key-value pair where the key is 'this.Publisher' and the value is an object containing 'numberOfPlayer' (hardcoded as 1) and 'goalScores' (taken from 'this.PlayerDetails[i].Goal_score').

```
76 // Map reduce function
77 var mapFunction = function() {
78     for (var i = 0; i < this.PlayerDetails.length; i++) {
79         var key = this.Publisher;
80         var value = { numberOfPlayer: 1, goalScores: this.PlayerDetails[i].Goal_score };
81
82         emit(key, value);
83     }
84 };
```

Figure 13: Query to create Map function

A screenshot of a code editor showing a JavaScript function named 'reduceFunction' starting at line 85. The function takes 'keyPublisher' and 'countObjectValues' as arguments. It initializes 'reducedValues' with 'numberOfPlayer' and 'goalScores' set to 0. It then iterates over 'countObjectValues' and accumulates the 'numberOfPlayer' and 'goalScores' for the given 'keyPublisher'.

```
85
86 var reduceFunction = function(keyPublisher, countObjectValues) {
87     reducedValues = { numberOfPlayer: 0, goalScores: 0 };
88
89     for (var i = 0; i < countObjectValues.length; i++) {
90         reducedValues.numberOfPlayer += countObjectValues[i].numberOfPlayer;
91         reducedValues.goalScores += countObjectValues[i].goalScores;
92     }
93
94     return reducedValues;
95 };
96
97
```

7. Show all the number of players with their publisher name.

The screenshot shows a code editor with a file named 'Coursework2-Task1.js'. The code is a MongoDB aggregation query. The query is as follows:

```
153
154 // Total number of players with their publisher name.
155 db.SayyedAbrarAkhtar_10272453_Games.aggregate([
156   {
157     $project:{
158       "Publisher":"$Publisher",
159       "Total Players": {"$size":"$PlayerDetails"}
160     }
161   }
162 ]);
163
```

Figure 23: Query to display all players with publisher name

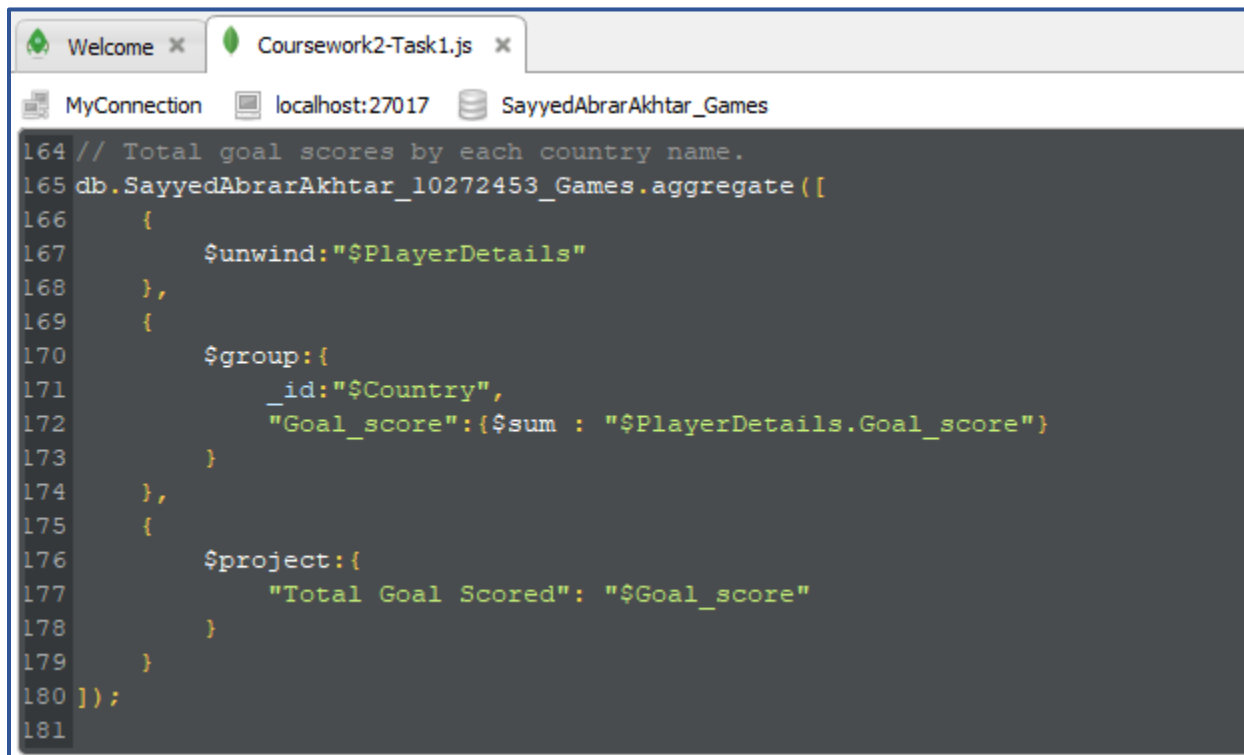

The screenshot shows the robo3t interface displaying the results of the MongoDB aggregation query. The results are shown in a table with three columns: Key, Value, and Type. The results are as follows:

Key	Value	Type
✓ (1) ObjectId("5f3ccf07aeaa4d05e62d4ddc")	{ 3 fields }	Object
_id	ObjectId("5f3ccf07aeaa4d05e62d4ddc")	ObjectId
Publisher	KOEI Co., Ltd.	String
Total Players	3	Int32
✓ (2) ObjectId("5f3ccf08aeaa4d05e62d4ddd")	{ 3 fields }	Object
_id	ObjectId("5f3ccf08aeaa4d05e62d4ddd")	ObjectId
Publisher	EIOI Co., Ltd.	String
Total Players	2	Int32
✓ (3) ObjectId("5f3ccf08aeaa4d05e62d4dde")	{ 3 fields }	Object

_id	ObjectId("5f3ccf08aeaa4d05e62d4ddf")	ObjectId
Publisher	Danone Co., Ltd.	String
Total Players	4	Int32

Figure 24: Shown all player with publisher name

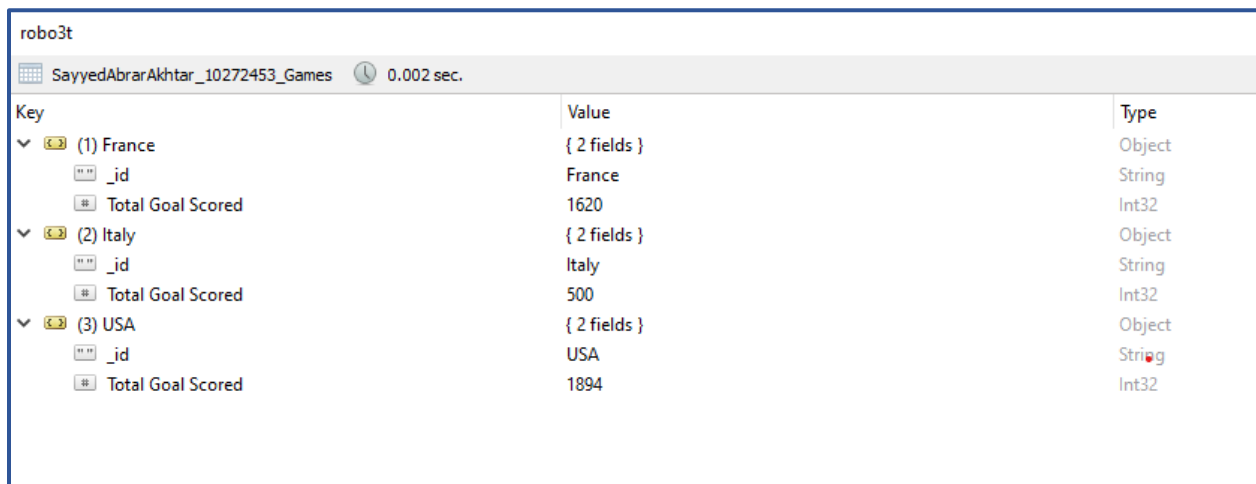

8. Show total goals scored by each country name.

The screenshot shows a code editor with two tabs: 'Welcome' and 'Coursework2-Task1.js'. The active tab contains a MongoDB aggregation query. The query is as follows:

```
164 // Total goal scores by each country name.
165 db.SayyedAbrarAkhtar_10272453_Games.aggregate([
166   {
167     $unwind: "$PlayerDetails"
168   },
169   {
170     $group: {
171       _id: "$Country",
172       "Goal_score": { $sum: "$PlayerDetails.Goal_score" }
173     }
174   },
175   {
176     $project: {
177       "Total Goal Scored": "$Goal_score"
178     }
179   }
180 ]);
181
```

Figure 25: Query to show total goal scored by each country

The screenshot shows the results of the MongoDB query in the robo3t interface. The results are displayed in a table with three columns: Key, Value, and Type. The data is grouped by country, showing the total goals scored for each.

Key	Value	Type
✓ (1) France	{ 2 fields }	Object
_id	France	String
Total Goal Scored	1620	Int32
✓ (2) Italy	{ 2 fields }	Object
_id	Italy	String
Total Goal Scored	500	Int32
✓ (3) USA	{ 2 fields }	Object
_id	USA	String
Total Goal Scored	1894	Int32

Task 2: Development of a graph database for a given dataset.

Find “Task_2_PremierLeague_2019.csv” file from the Moodle. The dataset contains information about the **English Premier League (EPL)** matches. You are expected to design and create a graph database to visualize the dataset and to answer the following queries:

1. Create a Data Model diagram for “Task_2_PremierLeague_2019.csv” dataset.

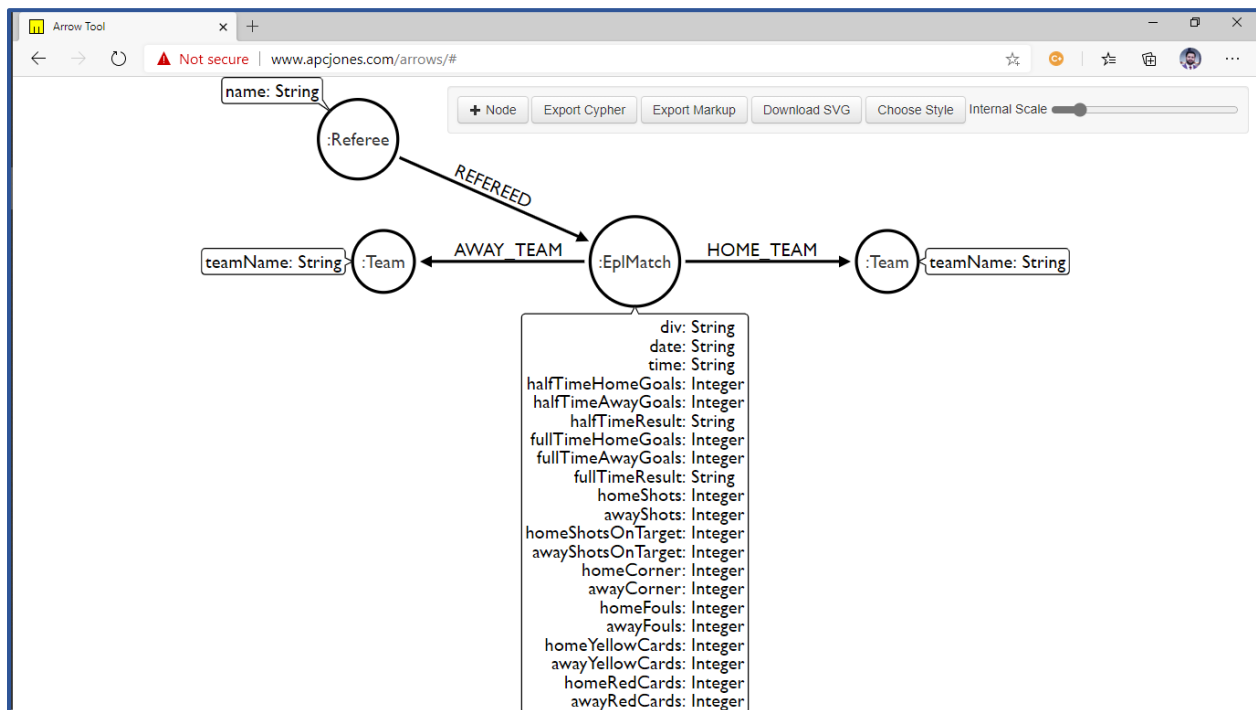

Figure 27: Data Model diagram of “Task_2_PremierLeague_2019.csv” dataset

2. Create nodes and relationship according to the Data Model which you have created in question no. 1.

```
1 // Query to create Nodes and Relationships
2 LOAD CSV WITH HEADERS FROM 'file:///Task_2_PremierLeauge_2019.csv' AS row
3 // Create Team nodes
4 MERGE(homeTeam:Team{teamName: row.`HomeTeam`})
5 MERGE(awayTeam:Team{teamName: row.`AwayTeam`})
6
7 // Create EplMatch nodes
8 MERGE(matches:EplMatch{div:row.`Div`, date:row.`Date`,
9 time: row.`Time`,
10 halfTimeHomeGoals: toInteger(row.`HTHG`),
11 halfTimeAwayGoals: toInteger(row.`HTAG`),
12 halfTimeResult: row.`HTR`,
13 fullTimeHomeGoals: toInteger(row.`FTHG`),
14 fullTimeAwayGoals: toInteger(row.`FTAG`),
15 fullTimeResult: row.`FTR`,
16 homeShots: toInteger(row.`HS`),
17 awayShots: toInteger(row.`AS`),
18 homeShotsOnTarget: toInteger(row.`HST`),
19 awayShotsOnTarget: toInteger(row.`AST`),
20 homeCorner: toInteger(row.`HC`),
21 awayCorner: toInteger(row.`AC`),
22 homeFouls: toInteger(row.`HF`),
23 awayFouls: toInteger(row.`AF`),
24 homeYellowCards: toInteger(row.`HY`),
25 awayYellowCards: toInteger(row.`AY`),
26 homeRedCards: toInteger(row.`HR`),
27 awayRedCards: toInteger(row.`AR`)
28 })
29
30 // Create relationship between EplMatch and Team nodes
31 MERGE (matches)-[:HOME_TEAM]->(homeTeam)
32 MERGE (matches)-[:AWAY_TEAM]->(awayTeam)
33
34 // Create Referee nodes
35 MERGE(referee:Referee{name: row.`Referee`})
36
37 // Create relationship between Referee and EplMatch
38 MERGE (referee)-[:REFEREED]->(matches)
```

Task 3:

“Column-oriented storage in a database system are more suitable for analytical reporting than the row-oriented database.” Justify this statement with suitable example.

With different memory hierarchy the latency cost related to it also differs. It determines various ways for storing and sharing data. Especially for analytical reporting or any other analytical application the orientation and alignment of data on the storage device can impact significantly.

In a row-oriented database all the values related to a specific row are stored consecutively in memory. Mostly row-oriented design is employed on traditional database. These designs are suitable for applications that works on manipulating any records related to a limited number of transactions at a time, like transaction processing applications.

On the other hand, big data analytics applications work on a large dataset. It performs scanning, aggregating, and summarizing of large datasets. To get a small set of columns, using multiway join and accessing complete rows will increase the execution time. Using a row-oriented design, to get a required attribute, complete records must be read which means it goes through more data than is needed to complete the request. Row-oriented design is usually misaligned with memory systems and as a result of increased access latencies. As well as, row-oriented design does not enable joins and aggregation required to execute analytical queries with desired level of performance.

That's the reason a column-oriented database is more preferred for analytical reporting. It helps to reduce the impacts of data latency. In column-oriented database, values for each column are stored separately which allows to access specific column values efficiently. [\(Loshin 2013\)](#)

The simplicity of the columnar approach provides many benefits over row-oriented database:

- Access performance:
Example: `SELECT SUM(INCOME) FROM WORKER;`
In column-oriented database looping over all the income values in a column and adding is faster by using single instruction multiple data (SIMD) techniques to do perform a parallel sum operation. Whereas the same operation will be slow in row-oriented database.
Whereas row-oriented database has limitations in diverse queries.
- Join and aggregation:
Example: `SELECT COUNT(*) FROM WORKER WHERE INCOME >= 100000 AND INCOME <= 200000;`
Parallel multiple unit processing, accessing and aggregating different columns increases the performance.
Whereas in row-oriented database the need for streaming entire records to find the join attributes hampers the performance severely.
- Compression:
Due to columnar layout of data, compression is easy to apply maintaining the performance without a significant decrease in storage.
Whereas in row-oriented database it is very difficult to apply compression that increases performance.

- Data loading speed:
Example: `SELECT SALES_ID, SHIPPING_ADDRESS FROM SALES_ACC WHERE LOCATION = 'KTM';`
Data is segregated by column in column-oriented database which allows the system to load columns in parallel using multiple threads.
Whereas in row-oriented database, all of the data values are stored together which prevent parallel processing.
